Index Terms—global localisation, 2D LIDAR, monte carlo, scan-to-map-scan matching

I. INTRODUCTION

Problem P. Let the unknown pose of an immobile 2D range sensor whose angular range is λ be $\mathbf{p}(x, y, \theta)$ with respect to the reference frame of map M . Let the range sensor measure range scan S_R . The objective is the estimation of \mathbf{p} given M , λ , and S_R .

II. DEFINITIONS

Let $\mathcal{A} = \{\alpha_i : \alpha_i \in \mathbb{R}\}$, $i \in \mathbb{I} = \langle 0, 1, \dots, n-1 \rangle$, denote a set of n elements, $\langle \cdot \rangle$ denote an ordered set, \mathcal{A}_\uparrow the set \mathcal{A} ordered in ascending order, the bracket notation $\mathcal{A}[\mathbb{I}] = \mathcal{A}$ denote indexing, and $\mathcal{A}_{k:l}$, $0 \leq k \leq l$, denote set $\{\mathcal{A}[k], \mathcal{A}[k+1], \dots, \mathcal{A}[l]\}$.

Definition I. Range scan captured from a 2D LIDAR sensor.—A conventional 2D LIDAR sensor provides a finite number of ranges, i.e. distances to objects within its range, on a horizontal cross-section of its environment, at regular angular and temporal intervals, over a defined angular range [1]. A range scan \mathcal{S} , consisting of N_s rays over an angular range λ , is an ordered map $\mathcal{S} : \Theta \rightarrow \mathbb{R}_{\geq 0}$, $\Theta = \{\theta_n \in [-\frac{\lambda}{2}, +\frac{\lambda}{2}] : \theta_n = -\frac{\lambda}{2} + \lambda \frac{n}{N_s}, n = 0, 1, \dots, N_s-1\}$. Angles θ_n are expressed relative to the sensor's heading, in the sensor's frame of reference.

Definition II. Map-scan.—A map-scan is a virtual scan that encapsulates the same pieces of information as a scan derived from a physical sensor. Only their underlying operating principle is different due to the fact the map-scan refers to distances to the boundaries of a point-set, referred to as the map, rather than within a real environment. A map-scan $S_V^M(\hat{\mathbf{p}})$ is derived by means of locating intersections of rays emanating from the estimate of the sensor's pose estimate $\hat{\mathbf{p}}$ and the boundaries of the map M .

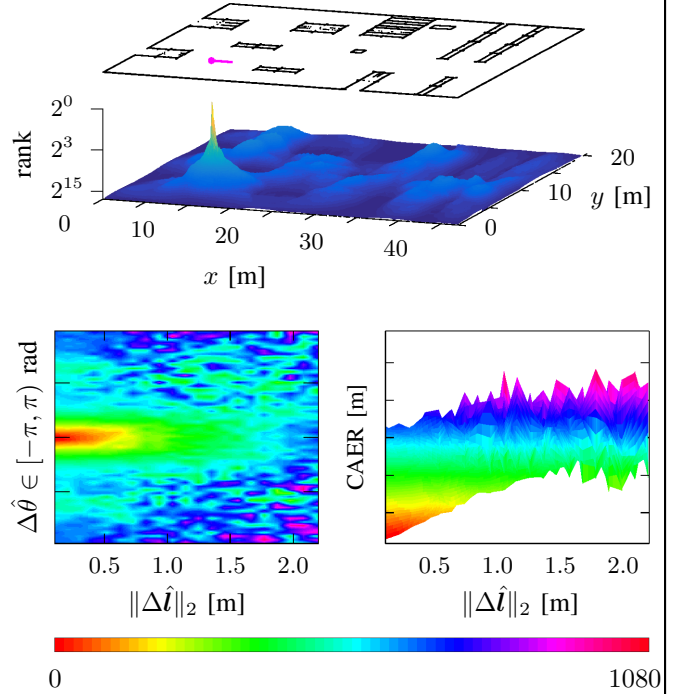

Fig. 1: Top: a map of an environment, the pose of a panoramic 2D LIDAR sensor (magenta), and the corresponding CAER rank field below them. Bottom: distribution of CAER values by location and orientation error of all sensor pose estimates corresponding to the rank field above, for estimate distances up to 2.0 m. CBGL leverages the relationships of (a) proportionality between the pose estimate error and the value of the CAER metric for pose estimates in a neighbourhood of the origin, and (b) lack of disproportionality outside of that neighbourhood: pose hypotheses dispersed within the map and ranked ascendingly according to the value of that metric produce a $\mathbf{r}(\text{rank})$ -field, which may be used to identify quickly and uniquely a pose estimate of the sensor

Definition III. CAER as metric.—Let S_p and S_q be two range scans, equal in angular range λ and size N_s . The value of the Cumulative Absolute Error per Ray (CAER) metric $\psi \in \mathbb{R}_{\geq 0}$ between S_p and S_q is given by

$$\psi(S_p, S_q) \triangleq \sum_{n=0}^{N_s-1} |S_p[n] - S_q[n]|$$

Definition IV. CAER as field.—A ψ -field on map M $f_\psi^M : \mathbb{R}^2 \times [-\pi, +\pi] \rightarrow \mathbb{R}_{\geq 0}$ is a mapping of 3D pose configurations $\hat{\mathbf{p}}(\hat{x}, \hat{y}, \hat{\theta})$ to CAER values (def. III) such that if $\psi(S_R, S_V^M(\hat{\mathbf{p}})) = c$ then $f_\psi^M(\hat{\mathbf{p}}) = c$. In other words a CAER field is produced by computing the value of the CAER metric between a range scan S_R (def. I) and a map-scan $S_V^M(\hat{\mathbf{p}})$ captured from pose configuration $\hat{\mathbf{p}}$ within map

M (def. II).

Definition V. Rank field.—Let f_ψ^M be a ψ -field on map M and $\mathcal{P} = \{\hat{p}_i\}$, $i \in \mathbb{I} = \langle 0, 1, \dots, |\mathcal{P}| - 1 \rangle$, be a set of 3D pose configurations within map M , such that $f_\psi^M(\mathcal{P}) = \Psi$. Let \mathbb{I}^* be the set of indices such that $\Psi[\mathbb{I}^*] = \Psi_\uparrow$. A r -field on map M $f_r^M : \mathbb{R}^2 \times [-\pi, +\pi] \rightarrow \mathbb{Z}_{\geq 0}$ is a mapping of 3D pose configurations \mathcal{P} to non-negative integers such that if $f_\psi^M(\mathcal{P}) = \Psi$ then $f_r^M(\mathcal{P}) = \mathbb{I}^*$ (equivalently: $f_r^M(\mathcal{P}[\mathbb{I}^*]) = \mathbb{I}$). In other words a rank field maps the elements of pose estimate set $\{\hat{p}_i\}$ to the ranks \mathbb{I}^* of their corresponding CAER values in hierarchy Ψ_\uparrow .

Definition VI. Field densities.—The locational and angular density, d_l and d_α respectively, of a ψ - or r -field express, correspondingly, the number of pose estimates per unit area of space and 2π rad.

III. RELATED WORK

IV. THE CBGL METHOD

The proposed method's foundations rest on observation O:

Observation O. It may be observed that there are conditions such that hypothesis H yields true.

Hypothesis H. Let the unknown pose of a 2D range sensor measuring range scan S_R (def. I) be $p(x, y, \theta)$ with respect to the reference frame of map M . Let \mathcal{H} be a set of pose hypotheses within the free (i.e. traversable) space of M : $\mathcal{H} = \{\hat{p}_i(\hat{x}_i, \hat{y}_i, \hat{\theta}_i)\} \subseteq \text{free}(M)$, $i = 0, 1, \dots, |\mathcal{H}| - 1$; \mathbb{S} be the set of map-scans (def. II) of M from pose hypotheses \mathcal{H} : $\mathbb{S} = \{S_V^M(\hat{p}_i)\}$; and Ψ be the set of CAERs (def. III) between S_R and the elements of \mathbb{S} : $\Psi = \{\psi(S_R, S_V^M(\hat{p}_i))\}$. Then there exist $\delta_0, \psi_0 \in \mathbb{R}_{>0}$ which define a set of pose estimates $\mathcal{V} \subseteq \mathcal{H}$ such that

$$\|p - \hat{p}_V\|_2 < \delta_0 \text{ and } \psi(S_R, S_V^M(\hat{p}_V)) < \psi_0$$

for all $\hat{p}_V \in \mathcal{V}$, for which

$$\psi(p, \hat{p}_V) < \psi(p, \hat{p}) \Leftrightarrow \|p - \hat{p}_V\|_2 < \|p - \hat{p}\|_2$$

for any $\hat{p} \in \mathcal{H} \setminus \mathcal{V} : \|p - \hat{p}\|_2 \geq \delta_0$.

Remark I. The composition of $\mathcal{H} = \mathcal{V} \cup \mathcal{X} \cup \mathcal{W}$, where $\mathcal{X} = \{\hat{p} \in \mathcal{H} \setminus \mathcal{V} : \|p - \hat{p}\|_2 \geq \delta_0\}$ and $\mathcal{W} = \{\hat{p} \in \mathcal{H} \setminus \mathcal{V} : \|p - \hat{p}\|_2 < \delta_0\}$. With respect to set $\mathcal{W} \dots$??
